# Transposes, permutations, spaces $R^n$

In this lecture we introduce vector spaces and their subspaces.

#### **Permutations**

Multiplication by a permutation matrix P swaps the rows of a matrix; when applying the method of elimination we use permutation matrices to move zeros out of pivot positions. Our factorization A = LU then becomes PA = LU, where P is a permutation matrix which reorders any number of rows of A. Recall that  $P^{-1} = P^{T}$ , i.e. that  $P^{T}P = I$ .

### **Transposes**

When we take the transpose of a matrix, its rows become columns and its columns become rows. If we denote the entry in row i column j of matrix A by  $A_{ij}$ , then we can describe  $A^T$  by:  $(A^T)_{ij} = A_{ji}$ . For example:

$$\left[\begin{array}{cc} 1 & 3 \\ 2 & 3 \\ 4 & 1 \end{array}\right]^T = \left[\begin{array}{ccc} 1 & 2 & 4 \\ 3 & 3 & 1 \end{array}\right].$$

A matrix A is *symmetric* if  $A^T = A$ . Given any matrix R (not necessarily square) the product  $R^T R$  is always symmetric, because  $(R^T R)^T = R^T (R^T)^T = R^T R$ . (Note that  $(R^T)^T = R$ .)

## **Vector spaces**

We can add vectors and multiply them by numbers, which means we can discuss *linear combinations* of vectors. These combinations follow the rules of a *vector space*.

One such vector space is  $\mathbb{R}^2$ , the set of all vectors with exactly two real number components. We depict the vector  $\begin{bmatrix} a \\ b \end{bmatrix}$  by drawing an arrow from the origin to the point (a,b) which is a units to the right of the origin and b units above it, and we call  $\mathbb{R}^2$  the "x-y plane".

Another example of a space is  $\mathbb{R}^n$ , the set of (column) vectors with n real number components.

### Closure

The collection of vectors with exactly two *positive* real valued components is *not* a vector space. The sum of any two vectors in that collection is again in the collection, but multiplying any vector by, say, -5, gives a vector that's not

in the collection. We say that this collection of positive vectors is *closed* under addition but not under multiplication.

If a collection of vectors is closed under linear combinations (i.e. under addition and multiplication by any real numbers), and if multiplication and addition behave in a reasonable way, then we call that collection a *vector space*.

### **Subspaces**

A vector space that is contained inside of another vector space is called a *subspace* of that space. For example, take any non-zero vector  $\mathbf{v}$  in  $\mathbb{R}^2$ . Then the set of all vectors  $c\mathbf{v}$ , where c is a real number, forms a subspace of  $\mathbb{R}^2$ . This collection of vectors describes a line through  $\begin{bmatrix} 0 \\ 0 \end{bmatrix}$  in  $\mathbb{R}^2$  and is closed under addition.

A line in  $\mathbb{R}^2$  that does not pass through the origin is *not* a subspace of  $\mathbb{R}^2$ . Multiplying any vector on that line by 0 gives the zero vector, which does not lie on the line. Every subspace must contain the zero vector because vector spaces are closed under multiplication.

The subspaces of  $\mathbb{R}^2$  are:

- 1. all of  $\mathbb{R}^2$ ,
- 2. any line through  $\begin{bmatrix} 0 \\ 0 \end{bmatrix}$  and
- 3. the zero vector alone (Z).

The subspaces of  $\mathbb{R}^3$  are:

- 1. all of  $\mathbb{R}^3$ ,
- 2. any plane through the origin,
- 3. any line through the origin, and
- 4. the zero vector alone (*Z*).

### Column space

Given a matrix A with columns in  $\mathbb{R}^3$ , these columns and all their linear combinations form a subspace of  $\mathbb{R}^3$ . This is the *column space* C(A). If  $A = \begin{bmatrix} 1 & 3 \\ 2 & 3 \\ 4 & 1 \end{bmatrix}$ , the column space of A is the plane through the origin in  $\mathbb{R}^3$  containing  $\begin{bmatrix} 1 \\ 2 \\ 4 \end{bmatrix}$  and  $\begin{bmatrix} 3 \\ 3 \\ 1 \end{bmatrix}$ .

Our next task will be to understand the equation  $A\mathbf{x} = b$  in terms of subspaces and the column space of A.
